

Title: An analytic research and review of the literature on practice of artificial intelligence in healthcare.

Summary:

AI has been an unbelievable influence on the state of modern medicine through a rapid development of technology. It is used to provide patient care. Mizna and colleagues published this review paper in the European Journal of Medical Research (2025). They provide a summary of the current landscape of each component of medicine affected by AI, like everything from robotic surgical systems to drug discovery and patient rehabilitation. One of the common aspects of this paper is AI-assisted robotic surgery systems like how the first-generation systems, such as the da Vinci Robotic Surgical System, have changed from basic need-based robotics into fully integrated environments. It can provide real-time decision support through the evolution of these devices. The authors provide various statistics addressing AI in surgery, such as; the reduced operating time for patients, fewer incidences of surgical error, and through some patients adequately recovering through functional capacity when compared to similar cases without the assistance of an AI technology. In addition, the authors also gives a compelling argument for patients who experience rehabilitation through AI technologies, such as robotic exoskeletons for stroke victims regaining motor function, wearables providing real-time tracking of recovery, and VR being utilized to provide cognitive rehabilitation experiences for patients. The use and measurements of these technologies are no longer predictive technologies; there are published articles to support their efficiency. The authors do address the challenges associated with the use of AI in health care delivery. The main challenge associated with using AI in health care continues to be consistent data quality. Medical records frequently contain wrong, incomplete information, which is a poor foundation.
