

Title: The ethics of AI in health care.

Summary:

This paper says the use of artificial intelligence in the healthcare sector. The impact of AI in healthcare is increasing day by day. It helps doctors in diagnosing illnesses, predicting potential health problems, keeping track of patients, and guiding treatment plans. AI can also bring about ethical concerns that are difficult to remove. The author says how AI has evolved from 2019 to 2024. AI may cause issues or mistakes because it learns from raw or uncleaned data. This can lead to incorrect result in diagnosis. The problem will more big when an error impacts many peoples rather than just one patient. Healthcare involves more than just data and predictions, it also includes trust, ethics, empathy, and human judgment. If doctors depend on AI too much , patients might feel that their care is less personal. In some cases, AI might even influence people's decisions without them being fully aware. A key concern is accountability. When an AI system causes harm, it is difficult to point out who is to blame. This could be the developers, healthcare professionals, or hospitals, making it unclear who is responsible. The authors do not disagree the use of AI in healthcare. Instead, they emphasize the need for clear regulations that keep pace with technological advancements. They believe that AI has the potential to show some meaningful information about healthcare, when transparency, responsibility, and patient wellbeing are prioritized in its development. Therefore, the main point is that AI cannot replace humans; it should help or work as an assistance of humans.
