

Title: Artificial Intelligence in Healthcare: Medical Students' Perspectives on Balancing Innovation, Ethics, and Patient-Centered Care

Summary:

This picture says that AI is capable of benefiting healthcare but not without the ethical foundation of its operation, transparency and active involvement of humans. There are three crucial issues: the protection of patient autonomy, the mitigation of algorithmic bias, and data privacy. The paper talks about how AI can help doctors to make decisions faster. It also notes that this can be a problem if patients do not understand what actually is happening. However, it emphasizes the necessity of active participation of clinicians in the decision-making process, since, again, AI should assist but not substitute doctors' judgement. Furthermore, the authors mention that the majority of AI solutions work like black boxes, therefore complicating the explanation process for both doctors and patients. One more issue in this picture is fairness. One example provided by the authors includes the lower effectiveness of an AI solution in cases of darker skin tones. There are also risk analysis tools that fail to identify the actual needs of black people. The authors provides the inclusion of A major theme is fairness. This paper also talks about data privacy issue. Hospitals and companies are using patient data to train AI tools, questions are emerging about consent, ownership and limits of data sharing. At last this paper also says that medical education have to change. Future doctors need to know about AI, ethics, communication, bias so that they can use AI tools more efficiently. So, we can say that AI must be deployed in a way that care patients and preserves trust.
